

# Ecological Outcomes Verification (EOV) for land regeneration

Ulf Ullring, Regenerativt Norge  
9. Dec 2021

# SUSTAINABILITY IS A BRIDGE. REGENERATION IS THE DESTINATION.

## Degenerating

Soil is degrading, biodiversity is decreasing, water is evaporating

## Sustainable

The land is in a steady, static state

## Regenerating

Soil is restored, biodiversity grows, water and carbon are absorbed

Regenerative agriculture is both process and result, but no metode.  
Regenerativity can be measured!

# EOV MEASURES THE HEALTH OF THE LAND AS A LIVING SYSTEM

DOWNLOAD PDF (v3.0)

## Soil Health

Healthy soils absorb more carbon, retain more water, and are richer in fertility

## Biodiversity

Plants are more varied and resilient, domestic animals and wildlife are more plentiful

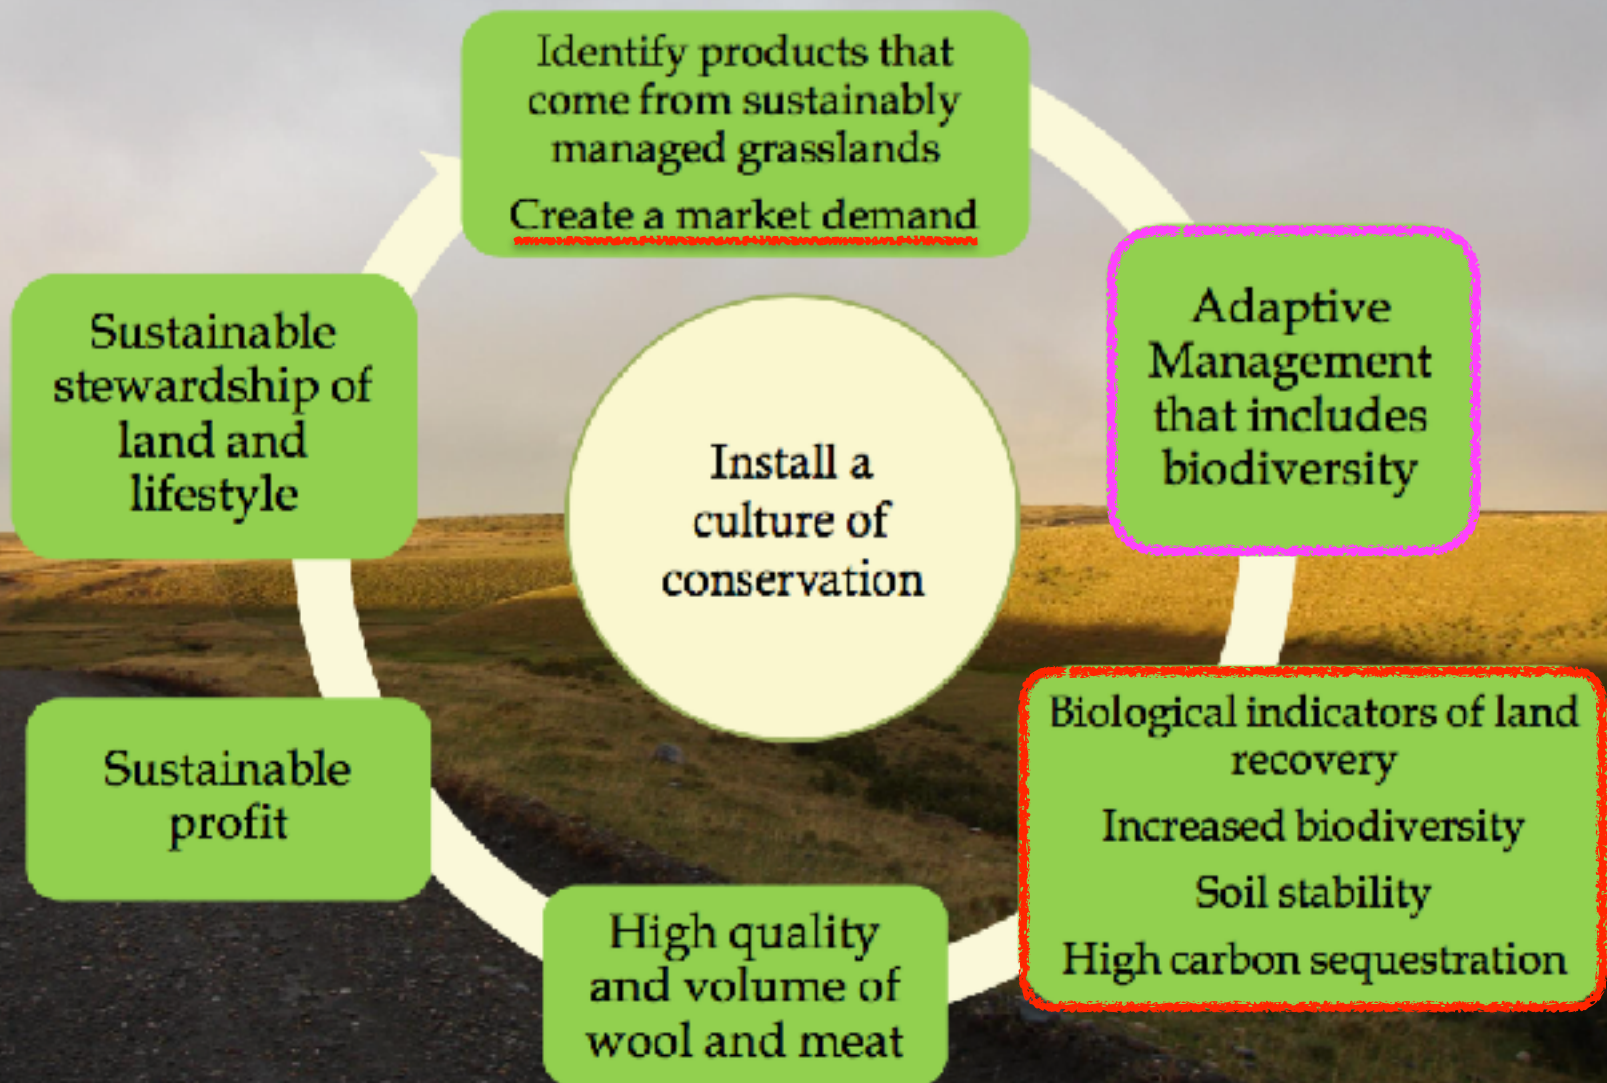

## Ecosystem Function

Water, minerals, nutrients and energy are cycled through a continual process of birth, growth, death and decay and back to birth again

# Our strategy: a market driven cultural change

# Land to Market

Land to Market is the world's first outcome-based, verified regenerative sourcing solution for meat, dairy, wool, leather, and ecosystem services. It offers a unique value proposition that is authentic, effective, and scalable. L2M packages the empirical data derived from EOQ, connects conscientious brand partners directly to EOQ supply, and supports them with education, storytelling, and communications strategies.

409 LANDBASES VERIFIED

**Abstract:** Grazing lands should be monitored to ensure their productivity and the preservation of ecosystem services. The study objective was to investigate the effectiveness of an Ecological Health Index (EHI) for assessing ecosystem ecological health in grazing lands. The EHI was developed by synthesizing existing vegetation and soil cover indicators. We implemented long-term transects at 44 farms from two ecological regions in Patagonia, the Humid Magellan Steppe (HMS) ( $n = 24$ ) and Subandean Grasslands (SG) ( $n = 20$ ), to collect data on established quantifiable vegetative and soil measurements and the EHI. Using known quantifiable measures, the HMS had numerically greater species richness compared to SG. Similarly, the average percentage of total live vegetation was more favorable in HMS. Correlating the EHI with these known quantifiable measures demonstrated positive correlations with species richness, the percentage of total live vegetation and carrying capacity and was negatively correlations with bare ground. These results suggest that EHI could be a useful method to detect the ecological health and productivity in grazing lands. Overall, we conclude that EHI is an effective short-term monitoring approach that ranchers could implement annually to monitor grazing lands and determine the impacts of ranch decision-making on important ecosystem indicators.

## TABLE OF RESULTS

Results come from input data sheet. Up to 30 paddocks. If more, you may need to create a second file or add new paddocks in input data sheet and create links with this table.  
 Hide lines or columns that are not necessary (business products or not evaluated attributes)  
 Do not overwrite green cells
